

**REVIEW 4 PRESENTATION**

# **Online Food Delivery Platform**

Results, technical implementation, innovation, social utility and sustainability

**Team 15 | Section 13 | Trimester 4, 2026-2027**

Mosangi Vijaya Lakshmi • Potlabathini Shashanth • D Pawan Kumar

### REVIEW 3

#### Order accuracy

Verify cart items, quantities, prices, taxes/charges and final order totals are consistent.

#### Group-bill accuracy

Verify participant items and individual payable amounts match the shared cart and final bill.

#### Status accuracy

Verify restaurant acceptance, delivery progress and customer-visible order status remain synchronized.

## Recommended evidence for Review 4

- Show a real order from cart → checkout → restaurant → delivery → completed status.
- Show a group order with at least two participants and compare item totals with the split amount.
- Show database records or an admin view that confirms the final order state.
- Record actual test cases and pass/fail results rather than only describing expected behavior.

### REVIEW 3

## Technical demonstration checklist

- Show frontend-to-backend API communication.
- Demonstrate database persistence after creating an order.
- Demonstrate a real-time event using two connected group-order participants.
- Explain authentication, role separation and how payment/location integrations fit into the architecture.

**Innovation: live group ordering**

A shared cart lets multiple users add items to one order in real time, followed by participant-level bill splitting.

**Innovation: real-time coordination**

Socket.io supports live order updates and delivery-related status communication.

**Sustainable architecture**

A database-backed modular web platform can be extended with more restaurants, users, delivery partners and services.

**Future sustainability enhancements**

- Digital receipts and order records reduce dependence on paper-based workflows.
- Group ordering can consolidate multiple users into a single delivery order.
- Analytics can help identify demand patterns and improve restaurant/delivery planning.
- Modular APIs make future features easier to add without replacing the complete system.

## Overall impact

**The proposed system brings multiple stakeholders into one digital workflow, improving coordination and visibility compared with phone-based ordering.**

REVIEW 3

Suggested test table

| Test case           | Expected result | Actual result      | Status      |
|---------------------|-----------------|--------------------|-------------|
| Customer order      | Should work     | Fill actual result | PASS / FAIL |
| Group split bill    | Should work     | Fill actual result | PASS / FAIL |
| Order status update | Should work     | Fill actual result | PASS / FAIL |
| Delivery tracking   | Should work     | Fill actual result | PASS / FAIL |

# Integration & Live Demonstration

## Live demo sequence

- Log in → browse restaurant → add food → checkout.
- Show the same order appearing in the restaurant workflow.
- Update order status and show the customer-side change.
- Create a group order and demonstrate two participants adding items in real time.
- Show the final participant split and completed order record.

# Future Enhancements & Sustainability Roadmap

Features that can strengthen the project beyond Review 4

## Key message

The strongest Review 4 story is measurable working results + clear technical evidence + the novel group-order experience.

# Conclusion

## A connected digital food-delivery ecosystem

**The project combines full-stack development, persistent database storage, real-time communication, location services, payments, and group ordering into one platform.**

- Accuracy: demonstrate measured and repeatable test results.
- Technical competence: prove frontend, backend, database and real-time integration.
- Innovation: highlight group ordering with live split bill.
- Utility: explain benefits for customers, restaurants, delivery partners and administrators.
- Sustainability: show a modular foundation and practical future extensions.
